# Szegő class for the finite gap case

For a probability measure  $\mu$  on  $\mathbb{C}$  with compact support  $S_{\mu}, |S_{\mu}| = \infty$ , we consider the orthonormal polynomials  $p_n(z, \mu) = \kappa_n z^n + \cdots$  with  $\kappa_n > 0$ . Then  $q_n = \kappa_n^{-1} p_n$  minimizes  $|| \cdot ||_2$  in  $\mathcal{M}_n = \{z^n + \cdots \}$ . We write  $\mu \in \operatorname{Reg}$  (regular in the Stahl-Totik sense) if  $\kappa_n^{1/n} \to \operatorname{Cap}(S_n)^{-1}$ . Here  $S_{\mu}$  may be polar. Let  $K = \bigcup_{k=1}^{N} [a_k, b_k]$  and  $d\mu = \omega(x) dx$  on K. By def.,  $\mu \in Sz(K)$  if  $I(\omega) = \int \log(\omega(x)) d\mu_K(x) > -\infty$ . For  $\mu \in Sz(K)$ , the polynomials  $p_n(\cdot, \mu)$  enjoy nice limit behaviour, stronger than for only regular  $\mu$ . Widom's characterization:  $\mu \in Sz(K) \iff \limsup_n W_n^2(\mu) > 0$ , where  $W_n^2(\mu) := ||q_n||_2 \operatorname{Cap}^{-n}(K) = \kappa_n^{-1} \operatorname{Cap}^{-n}(K)$  are Widom factors. There are similar results about Sz(K) for the case  $\mu = \mu_a + \mu_p$  (here a condition of Blaschke-type is added) and when K is a finite union of disjoint smooth Jordan curves or arcs. But, in general,  $\mu = \mu_a + \mu_p + \mu_{sc}$ .

**PROBLEM:** How to characterize  $Sz(S_{\mu})$  if  $\mu_{sc} \neq 0$ , for example  $\mu = \mu_{sc}$ ?

## OP for Cantor-type sets. The known results

M. Barnsley et al (1983, 85): OP on Julia polynomial sets;

G. Mantica (1996-15): numerical computing of Jacobi parameters for IFS;

S. Heilman, P. Owrutsky, R. Strichardz (2014): OP wrt self-similar measures (numerically);

J. Christiansen (2012): Parreau-Widom sets (they have positive Lebesgue measure);

H. Kruger & B. Simon (2015): some conjectures (based on numerical computing) about OP on the Cantor ternary set;

B. Simon et al. (80th-90th): almost periodic Schrödinger operators (discrete Schrödinger's operator is a particular case of Jacobi operator. Cantor-type sets appear as the spectral measures in some cases, e.g. in the one-dimensional quasi-crystal model or for the almost Mathieu operator with an irrational parameter).

Remark: in theoretical results orthogonal polynomials are taken mainly with respect to the equilibrium measure  $\mu_{K}$ .

<ロト < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

#### Weakly equilibrium Cantor sets

AG(2014): For  $\gamma = (\gamma_s)_{s=1}^{\infty}$  with  $0 < \gamma_s < \frac{1}{4}$  let  $r_0 = 1$  and  $r_s = \gamma_s r_{s-1}^2$ . Take  $P_2(x) = x(x-1)$  and  $P_{2^{s+1}} = P_{2^s} \cdot (P_{2^s} + r_s)$  for  $s \ge 1$ . Then  $K(\gamma) := \bigcap_{s=0}^{\infty} \overline{D}_s = \bigcap_{s=0}^{\infty} E_s = \bigcap_{s=0}^{\infty} \left(\frac{2}{r_s} P_{2^s} + 1\right)^{-1} ([-1, 1])$ , where  $D_s = \{z \in \mathbb{C} : |P_{2^s}(z) + r_s/2| < r_s/2\} \searrow$ , so we can apply the Harnack Principle, and  $E_s = \{x \in \mathbb{R} : |P_{2^s}(x) + r_s/2| \le r_s/2\} = \bigcup_{j=1}^{2^s} I_{j,s}$  is the inverse polynomial image. Here,  $P_{2^s} + r_s/2$  is the  $2^s$ -th Chebyshev polynomial on  $K(\gamma)$ . The set  $K(\gamma)$  has positive Lebesgue measure if  $\gamma_s$  are rather closed to  $\frac{1}{4}$ .

The set  $K(\gamma)$  has positive Lebesgue measure if  $\gamma_s$  are rather closed to  $\frac{1}{4}$ . Moreover, in the limit case  $\gamma_s = \frac{1}{4}$  for all s we have  $K(\gamma) = [0, 1]$ . At least for small  $\gamma$ , the set  $K(\gamma)$  is weakly equilibrium in the following sense. Let us distribute uniformly the mass  $2^{-s}$  on each  $I_{j,s}$  for  $j \leq 2^{-s}$ . Let  $\lambda_s$  be the normalized in this sense Lebesgue measure on  $E_s$ , so  $d\lambda_s = (2^{s}I_{i,s})^{-1}dt$  on  $I_{i,s}$ . Then  $\lambda_s \stackrel{*}{\to} \mu_{K(\gamma)}$  provided  $K(\gamma)$  is not polar.

# Some results for $K(\gamma)$

The representation  $g_{\mathbb{C}\setminus K(\gamma)}(z) = \lim_{s\to\infty} 2^{-s} \log |P_{2^s}(z)/r_s|$  for  $z \notin K(\gamma)$ allows to construct Green's functions with diverse moduli of continuity and sets with preassigned growth of subsequence of Markov's factors. AG 2014:  $\exists K \subset \mathbb{R}$ : the Markov inequality with the best Markov's exponent is not valid on K (a question posed by M. Baran et al.);  $\exists K$ : the best exponents in the local and the global versions of Markov's inequalities are essentially different (a question posed by L.Frerick et al.) G. Alpan & AG(2015):  $\mu_{K(\gamma)}$  and the corresponding Hausdorff measure are mutually absolutely continuous. This is not valid for symmetric Cantor-type sets, where these measures are mutually singular. (N. Makarov & A. Volberg (1986) for the classical Cantor set). AG and B. Hatinoğlu (2015): a set with any subexponential growth of Widom-Chebyshev factors and a set K for which  $(W_n(K))_{n=1}^{\infty}$  have highly irregular behaviour.

G. Alpan & AG, "OP on WECS": OP with respect to  $\mu_{K(\gamma)}$ .

# Orthogonal polynomials on $K(\gamma)$ . Main theorem

#### Theorem (1)

 $q_{2^{s}}(\cdot, \mu_{K(\gamma)})$  coincides with  $2^{s}$ -th Chebyshev polynomial for all s.

Sketch of the proof: Let  $\nu_s = 2^{-s} \sum_{k=1}^{2^s} \delta_{x_k}$ , where  $(x_k)_{k=1}^{2^s}$  are the zeros of  $P_{2^s} + r_s/2$  (they are simple and real). Then for s > m we can decompose all zeros  $(x_k)_{k=1}^{2^s}$  into  $2^{s-m-1}$  groups, on which the values of  $P_{2^m} + r_m/2$  are controllable. This gives  $\int \left(P_{2^m} + \frac{r_m}{2}\right) d\nu_s = 0$ . Since  $\nu_s \stackrel{*}{\to} \mu_{K(\gamma)}$  we have  $\int \left(P_{2^m} + \frac{r_m}{2}\right) d\mu_{K(\gamma)}$ . Similarly it was shown that  $\int \left( P_{2^{i_1}} + \frac{r_{i_1}}{2} \right) \left( P_{2^{i_2}} + \frac{r_{i_2}}{2} \right) \dots \left( P_{2^{i_n}} + \frac{r_{i_n}}{2} \right) d\nu_s = 0 \text{ for any indices}$  $0 \leq i_1 < \cdots < i_n < s$ . Each P of degree  $< 2^s$  is a linear combination of polynomials of the type  $(P_{2^{s-1}} + \frac{r_{s-1}}{2})^{n_{s-1}} \dots (P_2 + \frac{r_1}{2})^{n_1} (x - \frac{1}{2})^{n_0}$ . Therefore,  $q_{2^s}$  coincides with  $P_{2^s} + r_s/2$ . In addition, we have a simple representation  $||q_{2^s}||^2 = (1 - 2\gamma_{s+1}) r_s^2/4$ . Application of Newton's identities is a crucial point of the proof.

## Orthogonal polynomials on $K(\gamma)$ . Other values of n

In the next step, A-type and B-type polynomials were introduced. In particular, for  $2^m \leq n < 2^{m+1}$  with  $n = i_m 2^m + \cdots + i_0$  with  $i \in \{0, 1\}$  we take  $B_n = (q_{2^m})^{i_m} (q_{2^{m-1}})^{i_{m-1}} \dots (q_1)^{i_1}$ . The polynomials  $B_{(2k+1)\cdot 2^s}$  and  $B_{(2i+1)\cdot 2^m}$  are orthogonal for all  $j, k, m, s \in \mathbb{Z}_+$  with  $s \neq m$ . They can be considered as a basis in the set of polynomials: for each  $n \in \mathbb{N}$  with  $n = 2^{s}(2k + 1)$ , the polynomial  $q_n$  has a unique representation as a linear combination of  $B_{2^s}, B_{3\cdot 2^s}, B_{5\cdot 2^s}, \dots, B_{(2k-1)\cdot 2^s}, B_{(2k+1)\cdot 2^s}$ . This allows to present formulas to express coefficients of each  $q_n$ .

For example,  $B_{3\cdot 2^s} = q_{2^s}q_{2^{s+1}}$ , so  $q_{3\cdot 2^s} = q_{2^{s+1}}q_{2^s} - \frac{\|q_{2^{s+1}}\|^2}{\|q_{2^s}\|^2}q_{2^s}$ . Similarly,  $B_{5\cdot 2^s} = q_{2^s}q_{2^{s+2}}$  and  $q_{5\cdot 2^s} = c_0q_{2^s} + c_1q_{2^{s+1}}q_{2^s} + q_{2^s}q_{2^{s+2}}$  with

$$c_0 = \frac{||q_{2^{s+2}}||^2}{||q_{2^s}||^4 - ||q_{2^{s+1}}||^2}, \ c_1 = -c_0 \ \frac{||q_{2^s}||^2}{||q_{2^{s+1}}||^2}.$$

All coefficient can be expressed only in terms of  $(\gamma_k)_{k=1}^{\infty}$ . As k gets bigger, the complexity of calculations increases. In general, the polynomial  $q_n$  is not Chebyshev. (ロト・日本・日本・日本・日本・今日)

# Orthogonal polynomials on $K(\gamma)$ . Jacobi parameters

Jacobi parameters also can be calculated recursively:  $a_1 = ||q_1||$  and  $a_2 = ||q_2||/||q_1||$ . Suppose  $a_i$  are given for  $i \le n$ . If  $n + 1 = 2^s > 2$  then

$$a_{n+1} = \frac{||q_{2^s}||}{||q_{2^{s-1}}|| \cdot a_{2^{s-1}+1} \cdot a_{2^{s-1}+2} \cdots a_{2^s-1}}.$$

Otherwise,  $n+1=2^{s}(2k+1)$  for some  $s\in\mathbb{Z}_{+}$  and  $k\in\mathbb{N}.$  Here,

$$a_{n+1}^2 = a_{2^s(2k+1)}^2 = \frac{\|q_{2^s}\|^2 - a_{2^{s+1}k}^2 \cdots a_{2^{s+1}k-2^s+1}^2}{a_{2^s(2k+1)-1}^2 \cdots a_{2^{s+1}k+1}^2}$$

If  $\gamma_s \leq 1/6$  for all s hen  $\lim_{s \to \infty} a_{j \cdot 2^s + n} = a_n$  for  $j \in \mathbb{N}$  and  $n \in \mathbb{Z}_+$ . Here,  $a_0 := 0$ . In particular,  $\liminf_{n \to \infty} a_n = 0$ . The formulas can be applied as well for the case  $\gamma_n < 1/4$  for  $1 \leq n \leq s$ and  $\gamma_n = 1/4$  for n > s. Then  $K(\gamma) = E_s$  is a finite union of intervals. If

 $\gamma_n = 1/4$  for all *n* then  $K(\gamma) = [0, 1]$  and all  $a_n = 1/4$ , which corresponds to the case of the Chebyshev polynomials on this set.

#### Orthogonal polynomials on $K(\gamma)$ . Widom factors

Let  $W_n := W_n^2(\mu_{K(\gamma)}) = ||q_n|| / (Cap(K))^n$ . We have  $W_{2^s} > \sqrt{2}$  for each  $\gamma$ . If  $\gamma_n < 1/6$  for all s then  $\liminf_{n\to\infty} W_n = \liminf_{s\to\infty} W_{2^s} \ge \sqrt{6} \text{ and } \limsup_{n\to\infty} W_n = \infty.$ Next examples illustrate the behaviour of Widom factors: 1) If  $\gamma_n \to 0$  then  $W_{2^s} \to \infty$ . Therefore  $W_n \to \infty$ . 2) There exists  $\gamma_n \not\rightarrow 0$  with  $W_n \rightarrow \infty$ . One can take  $\gamma_{2k} = 1/6, \ \gamma_{2k-1} = 1/k.$ 3) If  $\gamma_n \ge c > 0$  for all *n* then  $\liminf_{n \to \infty} W_n \le 1/2c$ . 4) There exists  $\gamma$  with  $\inf \gamma_n = 0$  and  $\liminf_{n \to \infty} W_n < \infty$ . Here we can take  $\gamma_n = 1/6$  for  $n \neq n_k$  and  $\gamma_{n_k} = 1/k$  for a sparse sequence  $(n_k)_{k=1}^{\infty}$ . Then  $(W_{2^{n_k}})_{k=1}^{\infty}$  is bounded. Later it was shown that  $K(\gamma)$  is a Parreau-Widom set if and only if  $\sum_{n=1}^{\infty} \sqrt{\frac{1}{4} - \gamma_n} < \infty.$

#### Orthogonal polynomials on generalized Julia sets

Let  $(f_n(z))_{n=1}^{\infty}$  be a sequence of rational functions with deg  $f_n \ge 2$ . in  $\overline{\mathbb{C}}$ . Let us define  $F_n(z) := f_n \circ F_{n-1}(z)$  recursively for  $n \ge 1$  and  $F_0(z) = z$ . Then the Fatou set  $F_{(f_n)}$  is defined as the domain of normality for  $(F_n)_{n=1}^{\infty}$  in the sense of Montel, its complement  $J_{(f_n)}$  is the Julia set. If  $f_n = f$  for some fixed rational f for all n then we have autonomous F(f) and J(f).

M. F. Barnsley, J. S. Geronimo, A. N. Harrington (1982, 83) presented  $q_{k\cdot n}(\cdot, \mu_{J(f)}), k \in \mathbb{N}$  for  $f = z^n + \cdots$ .

We (with G. Alpan) extend this result to  $J_{(f_n)}$  for a regular in the Brück -Büger sense polynomial sequence  $(f_n)$ . Also this is a generalization of the "OP on WECS": if we take  $f_n(z) = \frac{1}{2\gamma_n}(z^2 - 1) + 1$  for all n, then  $K_1(\gamma) := J_{(f_n)}$  is a stretched version of the set  $K(\gamma)$ .

◆□> ◆圖> ◆臣> ◆臣> □臣

#### Towards the Szegő class

In the finite gap case (some additional mass points fast converging to the essential support are allowed) we have

$$\int \log[d\mu/dx] \, d\mu_{\mathcal{K}}(x) > -\infty \iff \limsup_{n \to \infty} W_n^2(\mu) > 0.$$

The Szegő condition on the left means that the corresponding integral converges. This condition cannot be applied to singular continuous measures, whereas the Widom condition  $(W_n^2(\mu) \nrightarrow 0)$  is applicable to any measure, even with a polar support. The Widom condition is the main candidate to characterize the Szegő class in the general case. Therefore the analysis of Widom factors for small sets, especially for  $\mu \neq \mu_K$ , is rather interesting.

・ロン ・四と ・日と ・日

# Conjectures

1) If a compact set K is regular with respect to the Dirichlet problem then  $\mu_K$  always belongs to the Szegő class (in its Widom's description). Remark:  $\mu_K \in \mathbf{Reg}$ ; in known cases  $W_n^2(\mu_K) > a > 0$  for all n. 2) In the case of measures with non-polar support K, the Szegő condition should be done as  $I(\mu) := \int \log(d\mu/d\mu_K) d\mu_K > -\infty$ . Arguments in favour:

 $\mu_K$  is the most natural measure in the theory of general OP; this condition coincides with the Szegő condition in known cases; by Jensen's inequality, the value  $I(\mu)$  is nonpositive and it attains its maximum 0 just in the case  $\mu = \mu_K$ ;

 $I(\mu)$  is exactly the relative entropy of  $\mu_{\mathcal{K}}$  with respect to  $\mu$ .

Objections (based on the numerical evidence from H. Krüger & B. Simon): (*a<sub>n</sub>*) were calculated for  $n \le 200.000$  in the case  $\mu_{CL}$  on the classical Cantor set  $K_0$ . For these values  $W_n^2(\mu_{CL})$  behave as a bounded below (by a positive number) sequence. But  $\mu_{CL} \perp \mu_{K_0}$  and  $I(\mu) = -\infty$ .
